

# Radio transients (and radio variables ( and the interstellar medium ))

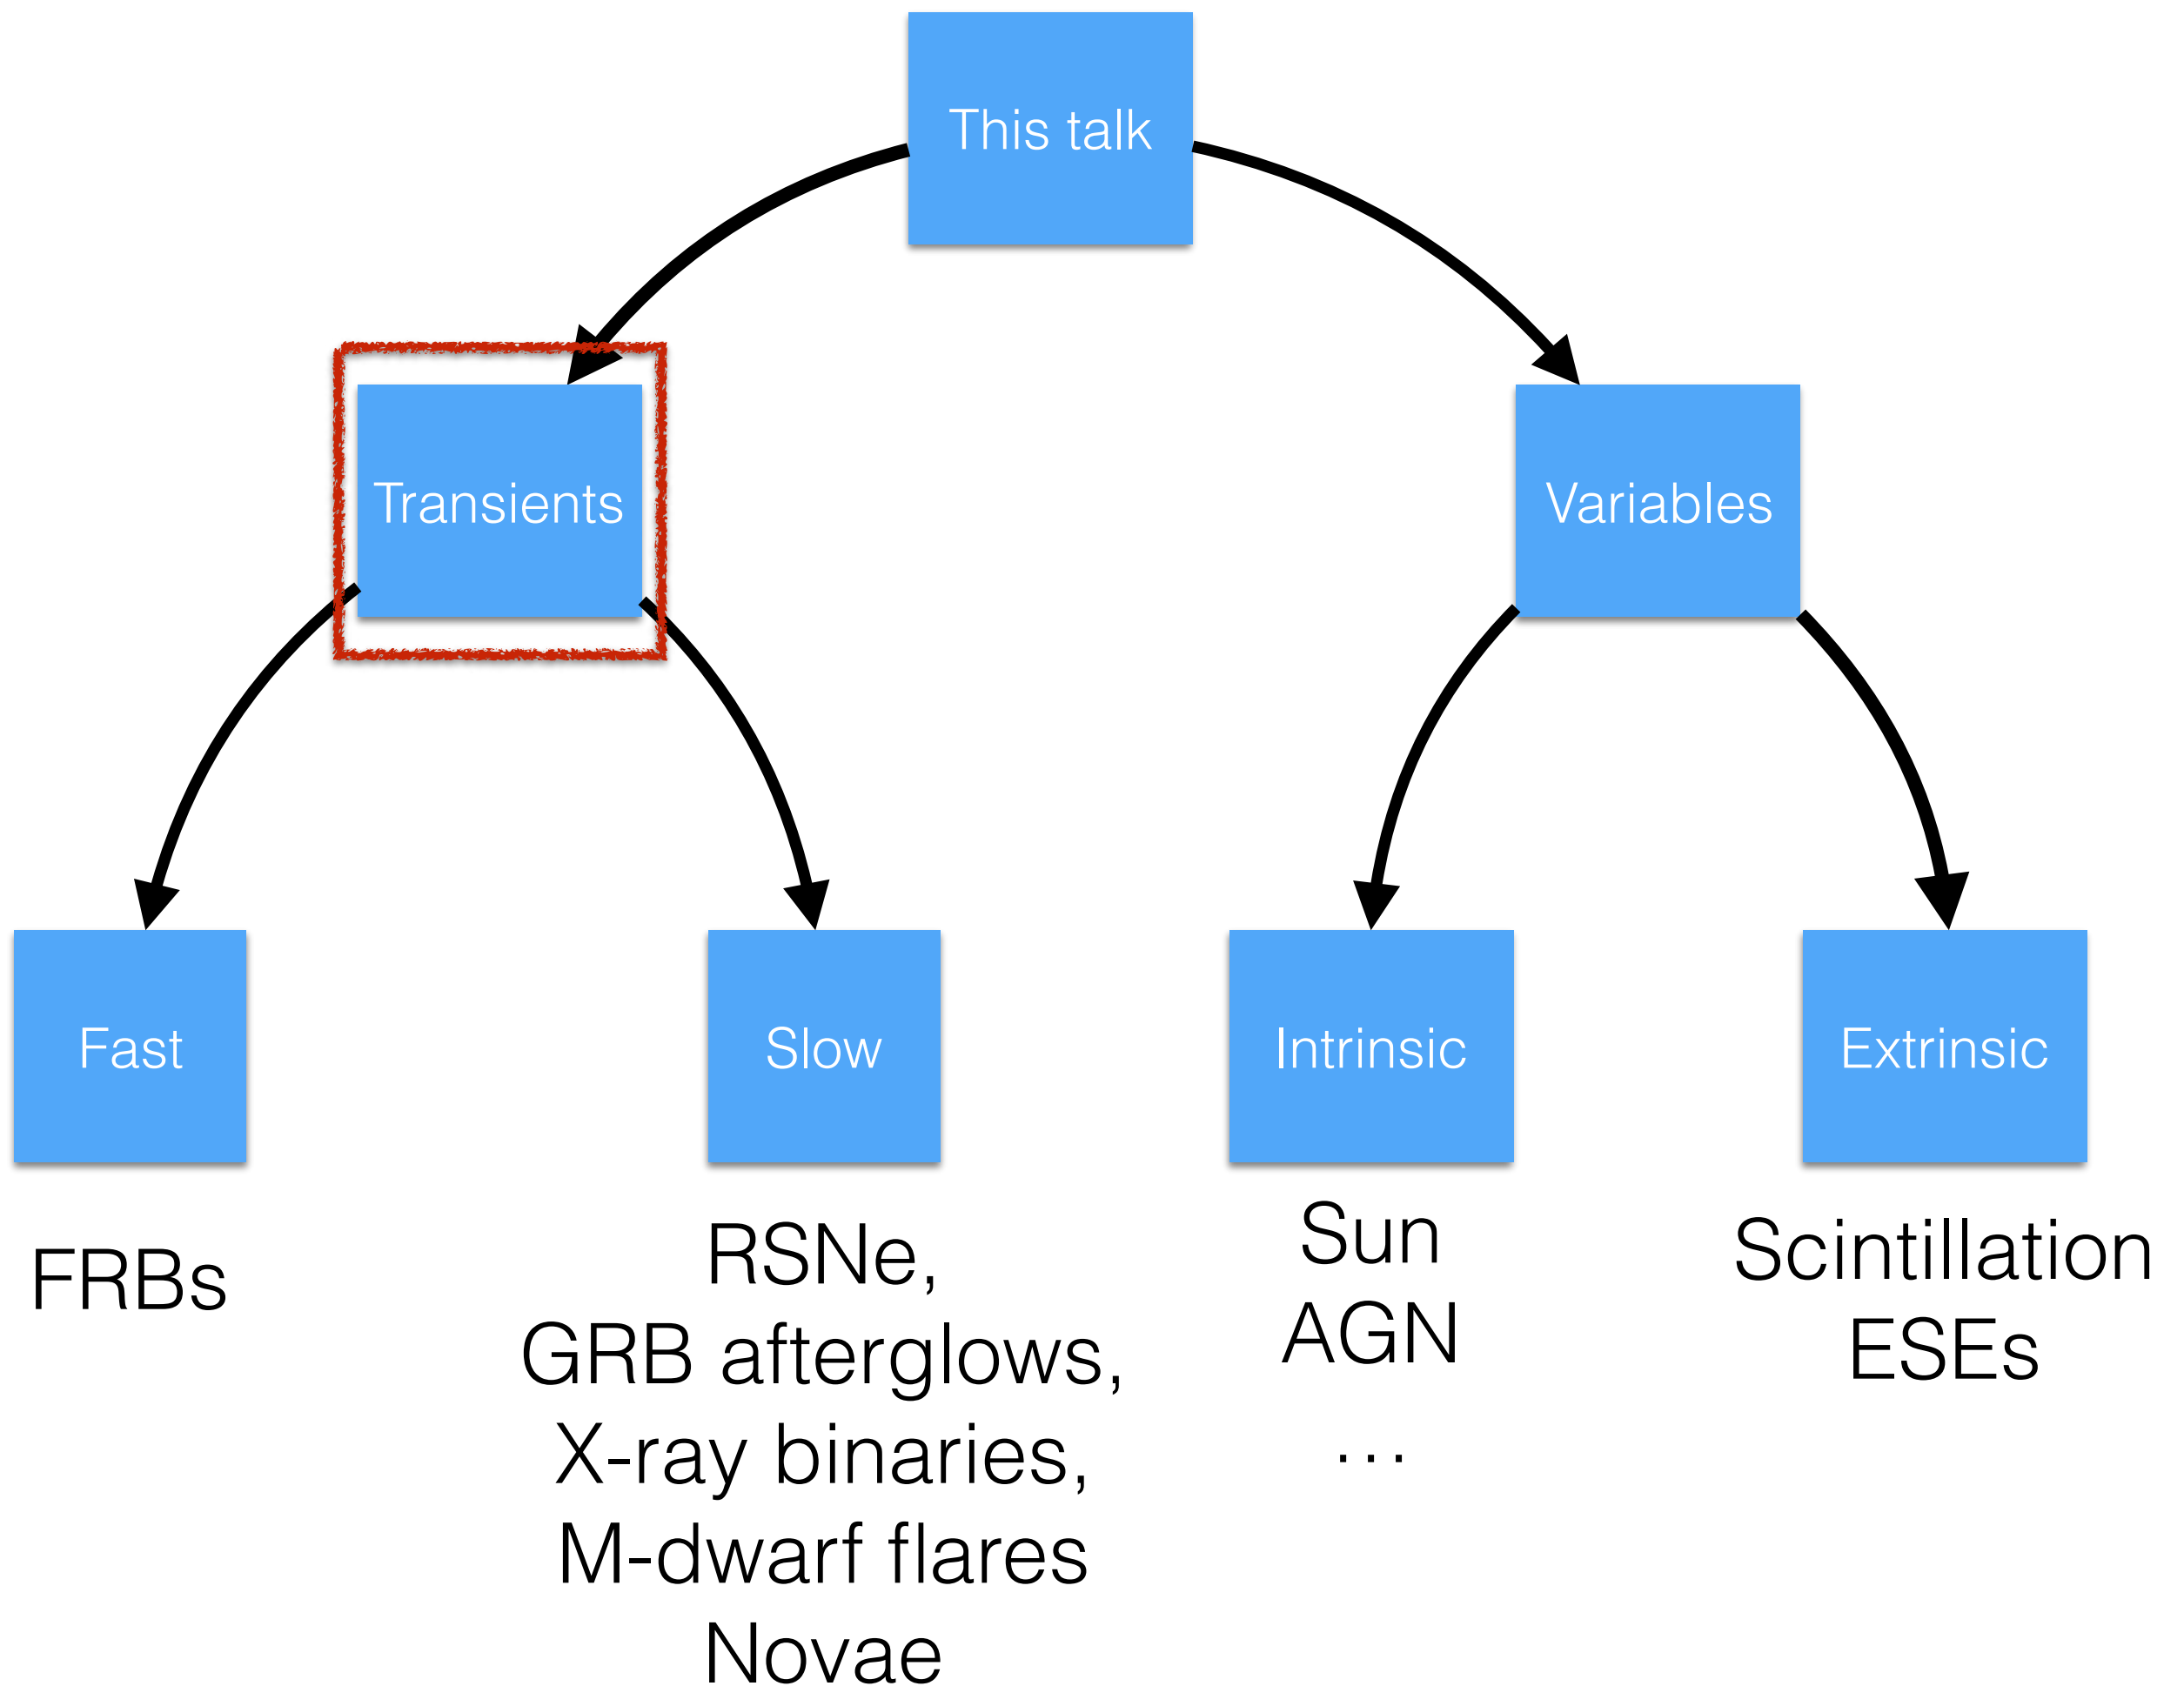

Keith Bannister (ATNF)  
ATNF Radio School 2017

# Warning

There's a huge amount of different science on this topic.

This is just a flavour.

Frequency / Energy

Frequency / Energy

# Dispersion

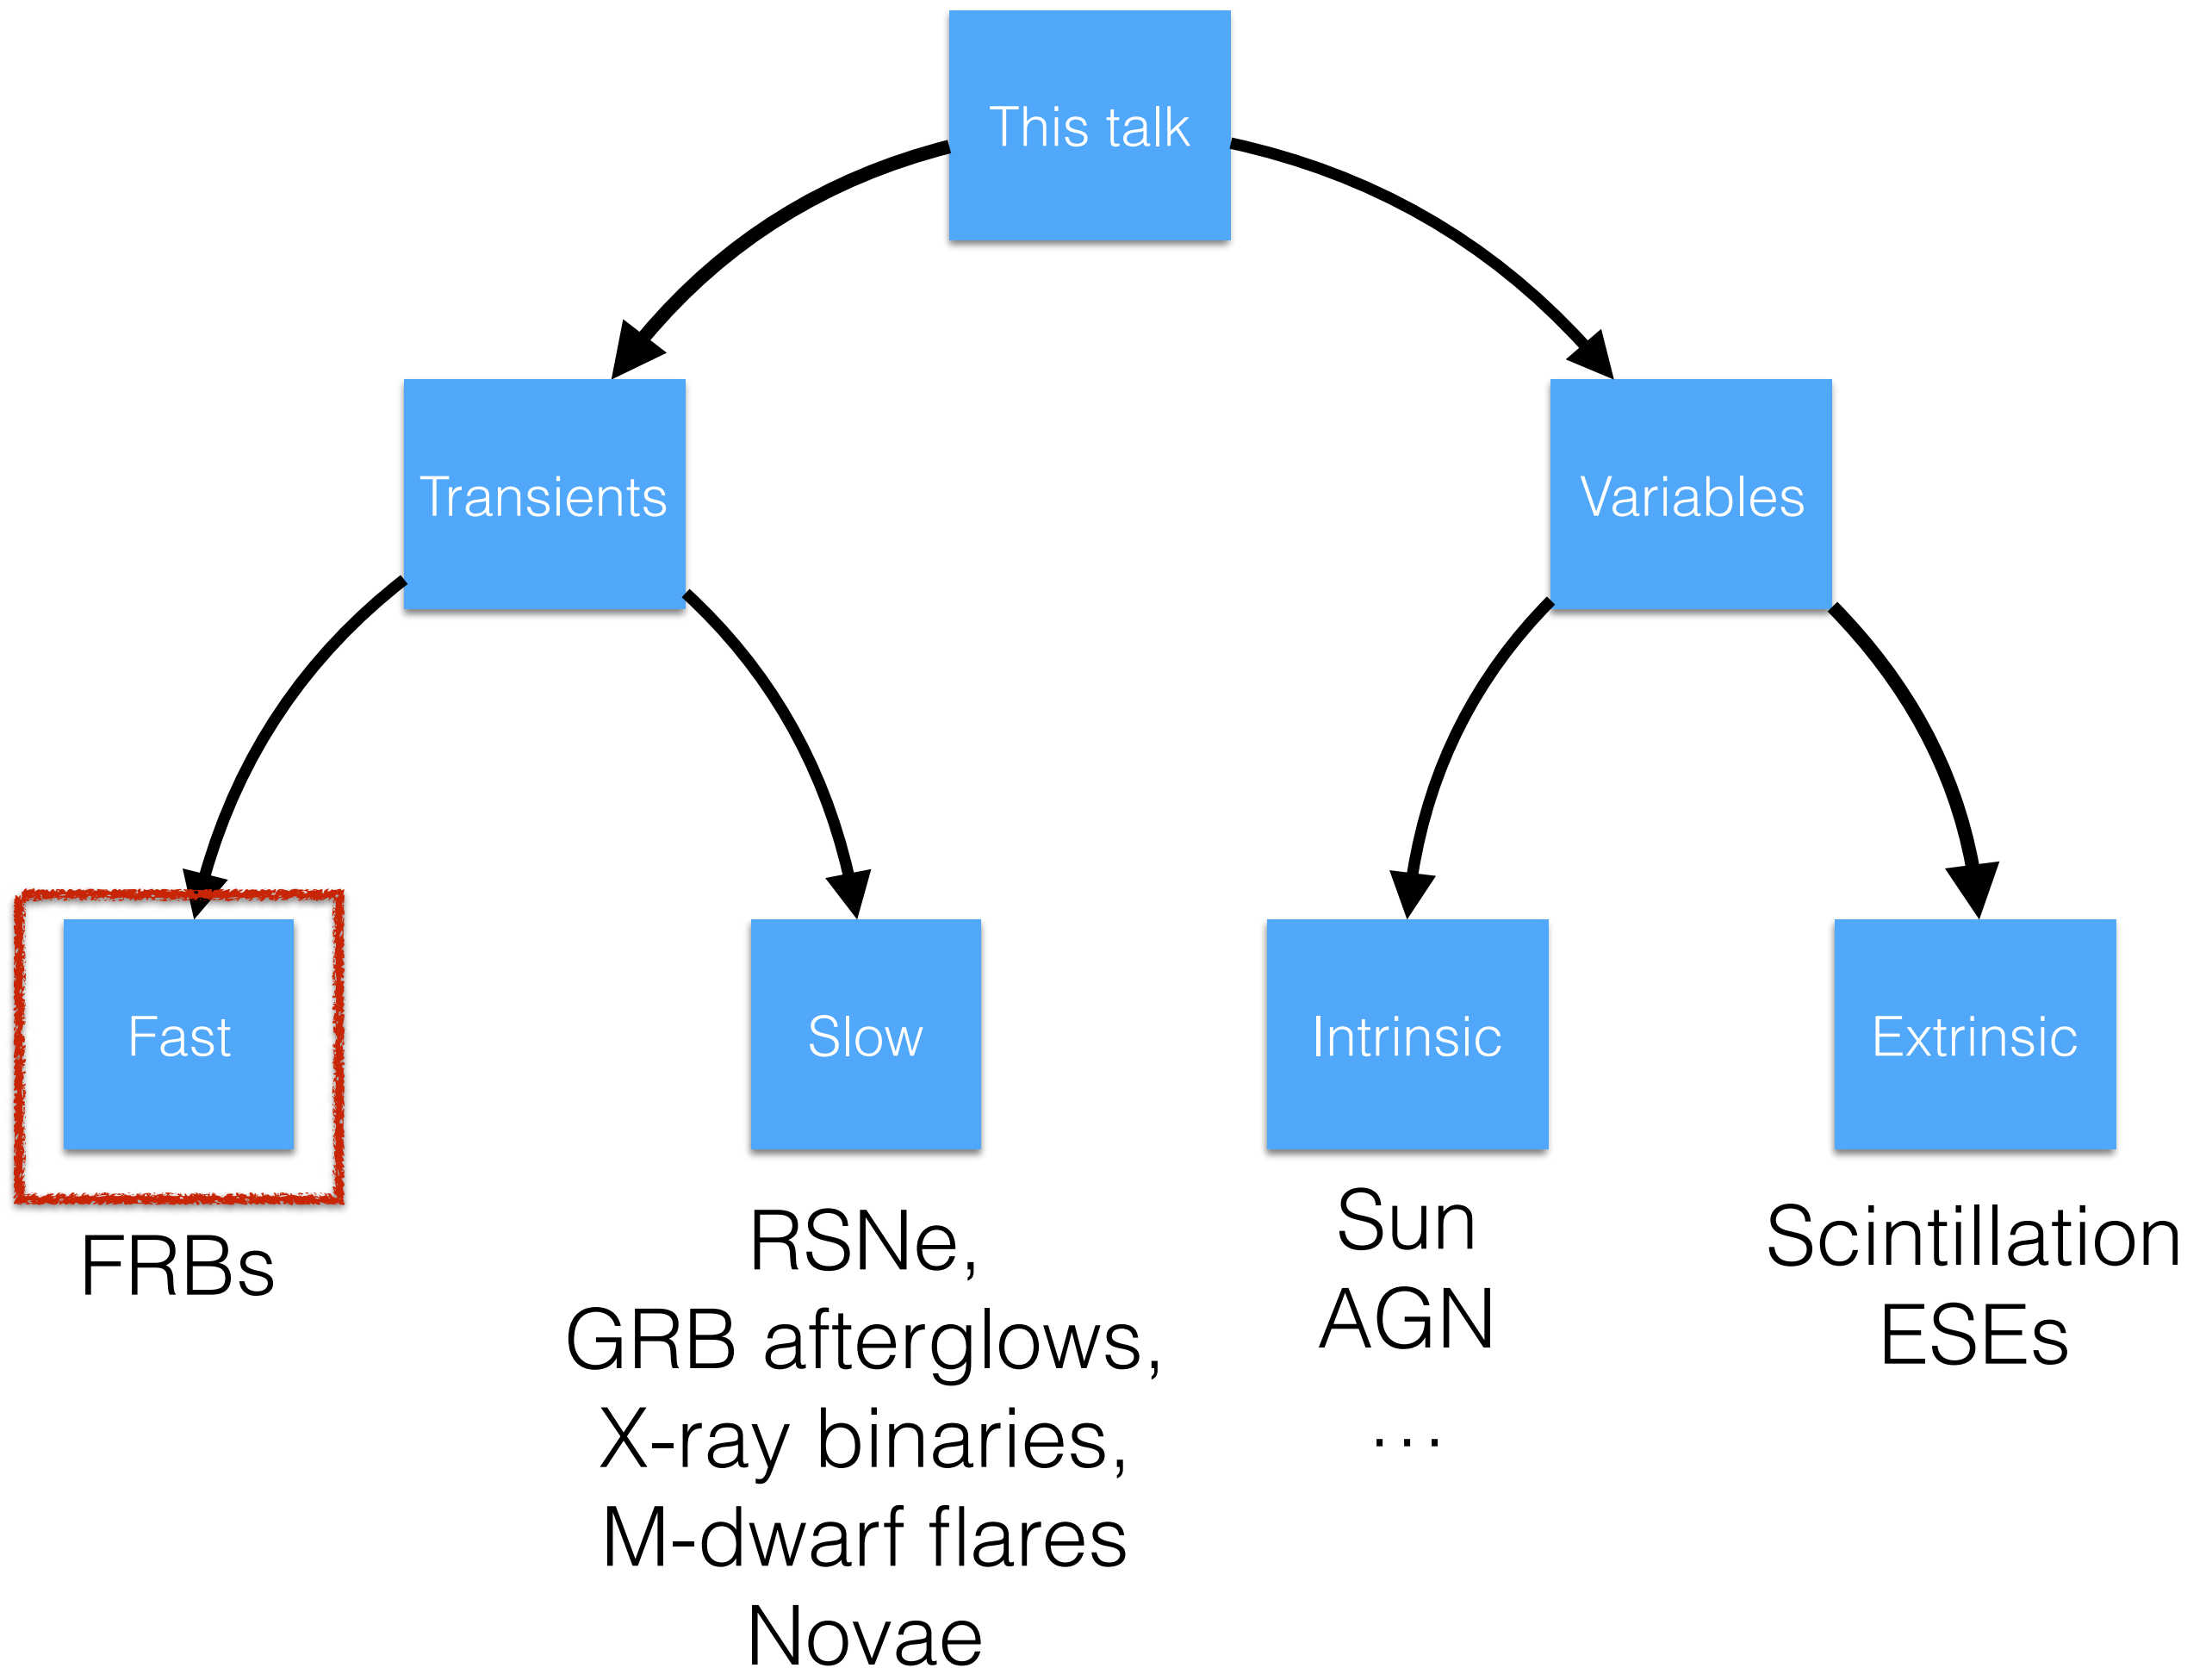

$$\frac{\Delta t}{\text{ms}} = 4.15 \text{DM} \left( \left( \frac{\nu_1}{\text{GHz}} \right)^{-2} - \left( \frac{\nu_2}{\text{GHz}} \right)^{-2} \right)$$

$$DM = \int_0^{\text{source}} n_e dl$$

Frequency

Time

# Fast Radio Bursts

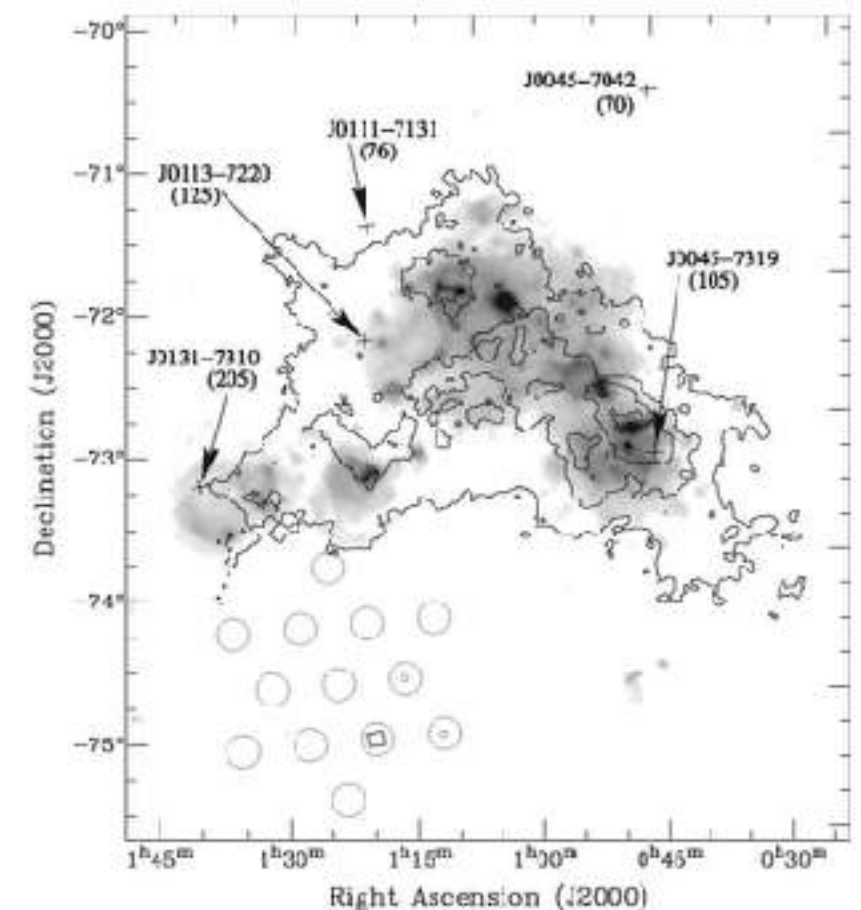

After 10 years, we still don't know what they are

# Fast Radio Bursts

$$\Delta t = 4.15 \text{DM} (\nu_1^{-2} - \nu_2^{-2}) (\text{ms})$$

- Data recorded in 2001, but only discovered in 2007 (**old data is useful!**)
- Super bright:  $\gg 30 \text{ Jy ms}$ .
- Saturated 1 beam - found in 2 others
- Dispersion Measure  $\gg$  than expected from the Milky Way and SMC
- \*was\* being looked for, but they were lucky not to delete it by accident: **be careful with your processing**

# Perytons

Katherine Capach

- Looked like FRBs
- Frequency-swept signal
- Found in all beams -> Terrestrial?
- Strong frequency structure
- What does this mean for the original FRB?

# The d(r)ought breaks

- 4 more FRBs at Parkes
- Single beam
- Range of dispersion measures
- Good fit to cold plasma dispersion
- 5 more thereafter
- Why only Parkes?
- Are these just less weird Perytons?

Thornton+ 13

# Perytons resolved!

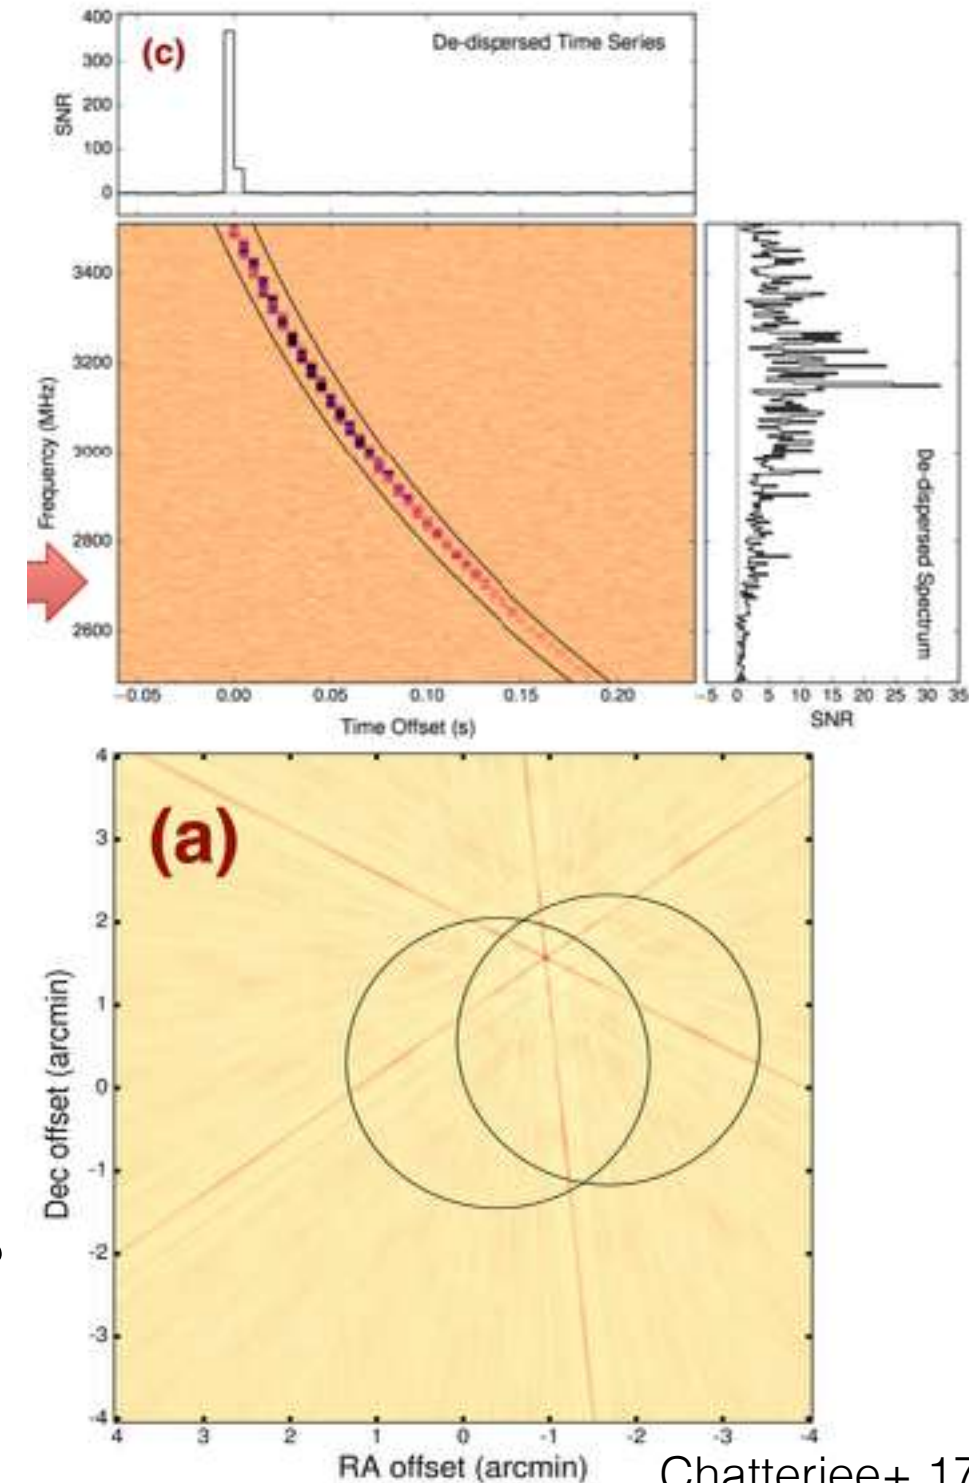

- RFI monitoring system installed (thanks Jamie! **Work with site staff & engineers - they're handy!**)
- A bit of background knowledge on how microwave ovens work.
- Resolved thanks to careful RFI monitoring and a cold lunch - **know your telescope and your environment.**
- But is the Lorimer burst real?
- Why only Parkes?

# “The Repeater”

- First discovered at Arecibo
- Discovered to repeat in follow-up observations
- Localised to  $\ll 1$  arc second by the VLA
- Fringes on intercontinental baselines (VLBI)
- Located in a star-forming (H $\alpha$  bright) region in a dwarf galaxy at  $z=0.2$  (1 Gpc!)
- Co-incident with a persistent, non-variable radio source
- Similar place to where we find long gamma ray bursts and super luminous supernovae - related?

# Where are we now?

- 24 published bursts (Sep 2017)
- Largest DM = 2700 pc/cm<sup>3</sup> (!)
- Ntheories > Nbursts
- Most localised to ~ 30 arcmin (Parkes)
- No afterglows discovered - even with a \*lot\* of follow-up.
- 1 repeater. Localised to ~millarcseconds
- >10 telescopes around the world searching for FRBs
- We want: more FRBs with ~arcsecond positions to get:
  - Better understanding of the population
  - Measurement of DM vs  $z$  -> Baryon content of the universe

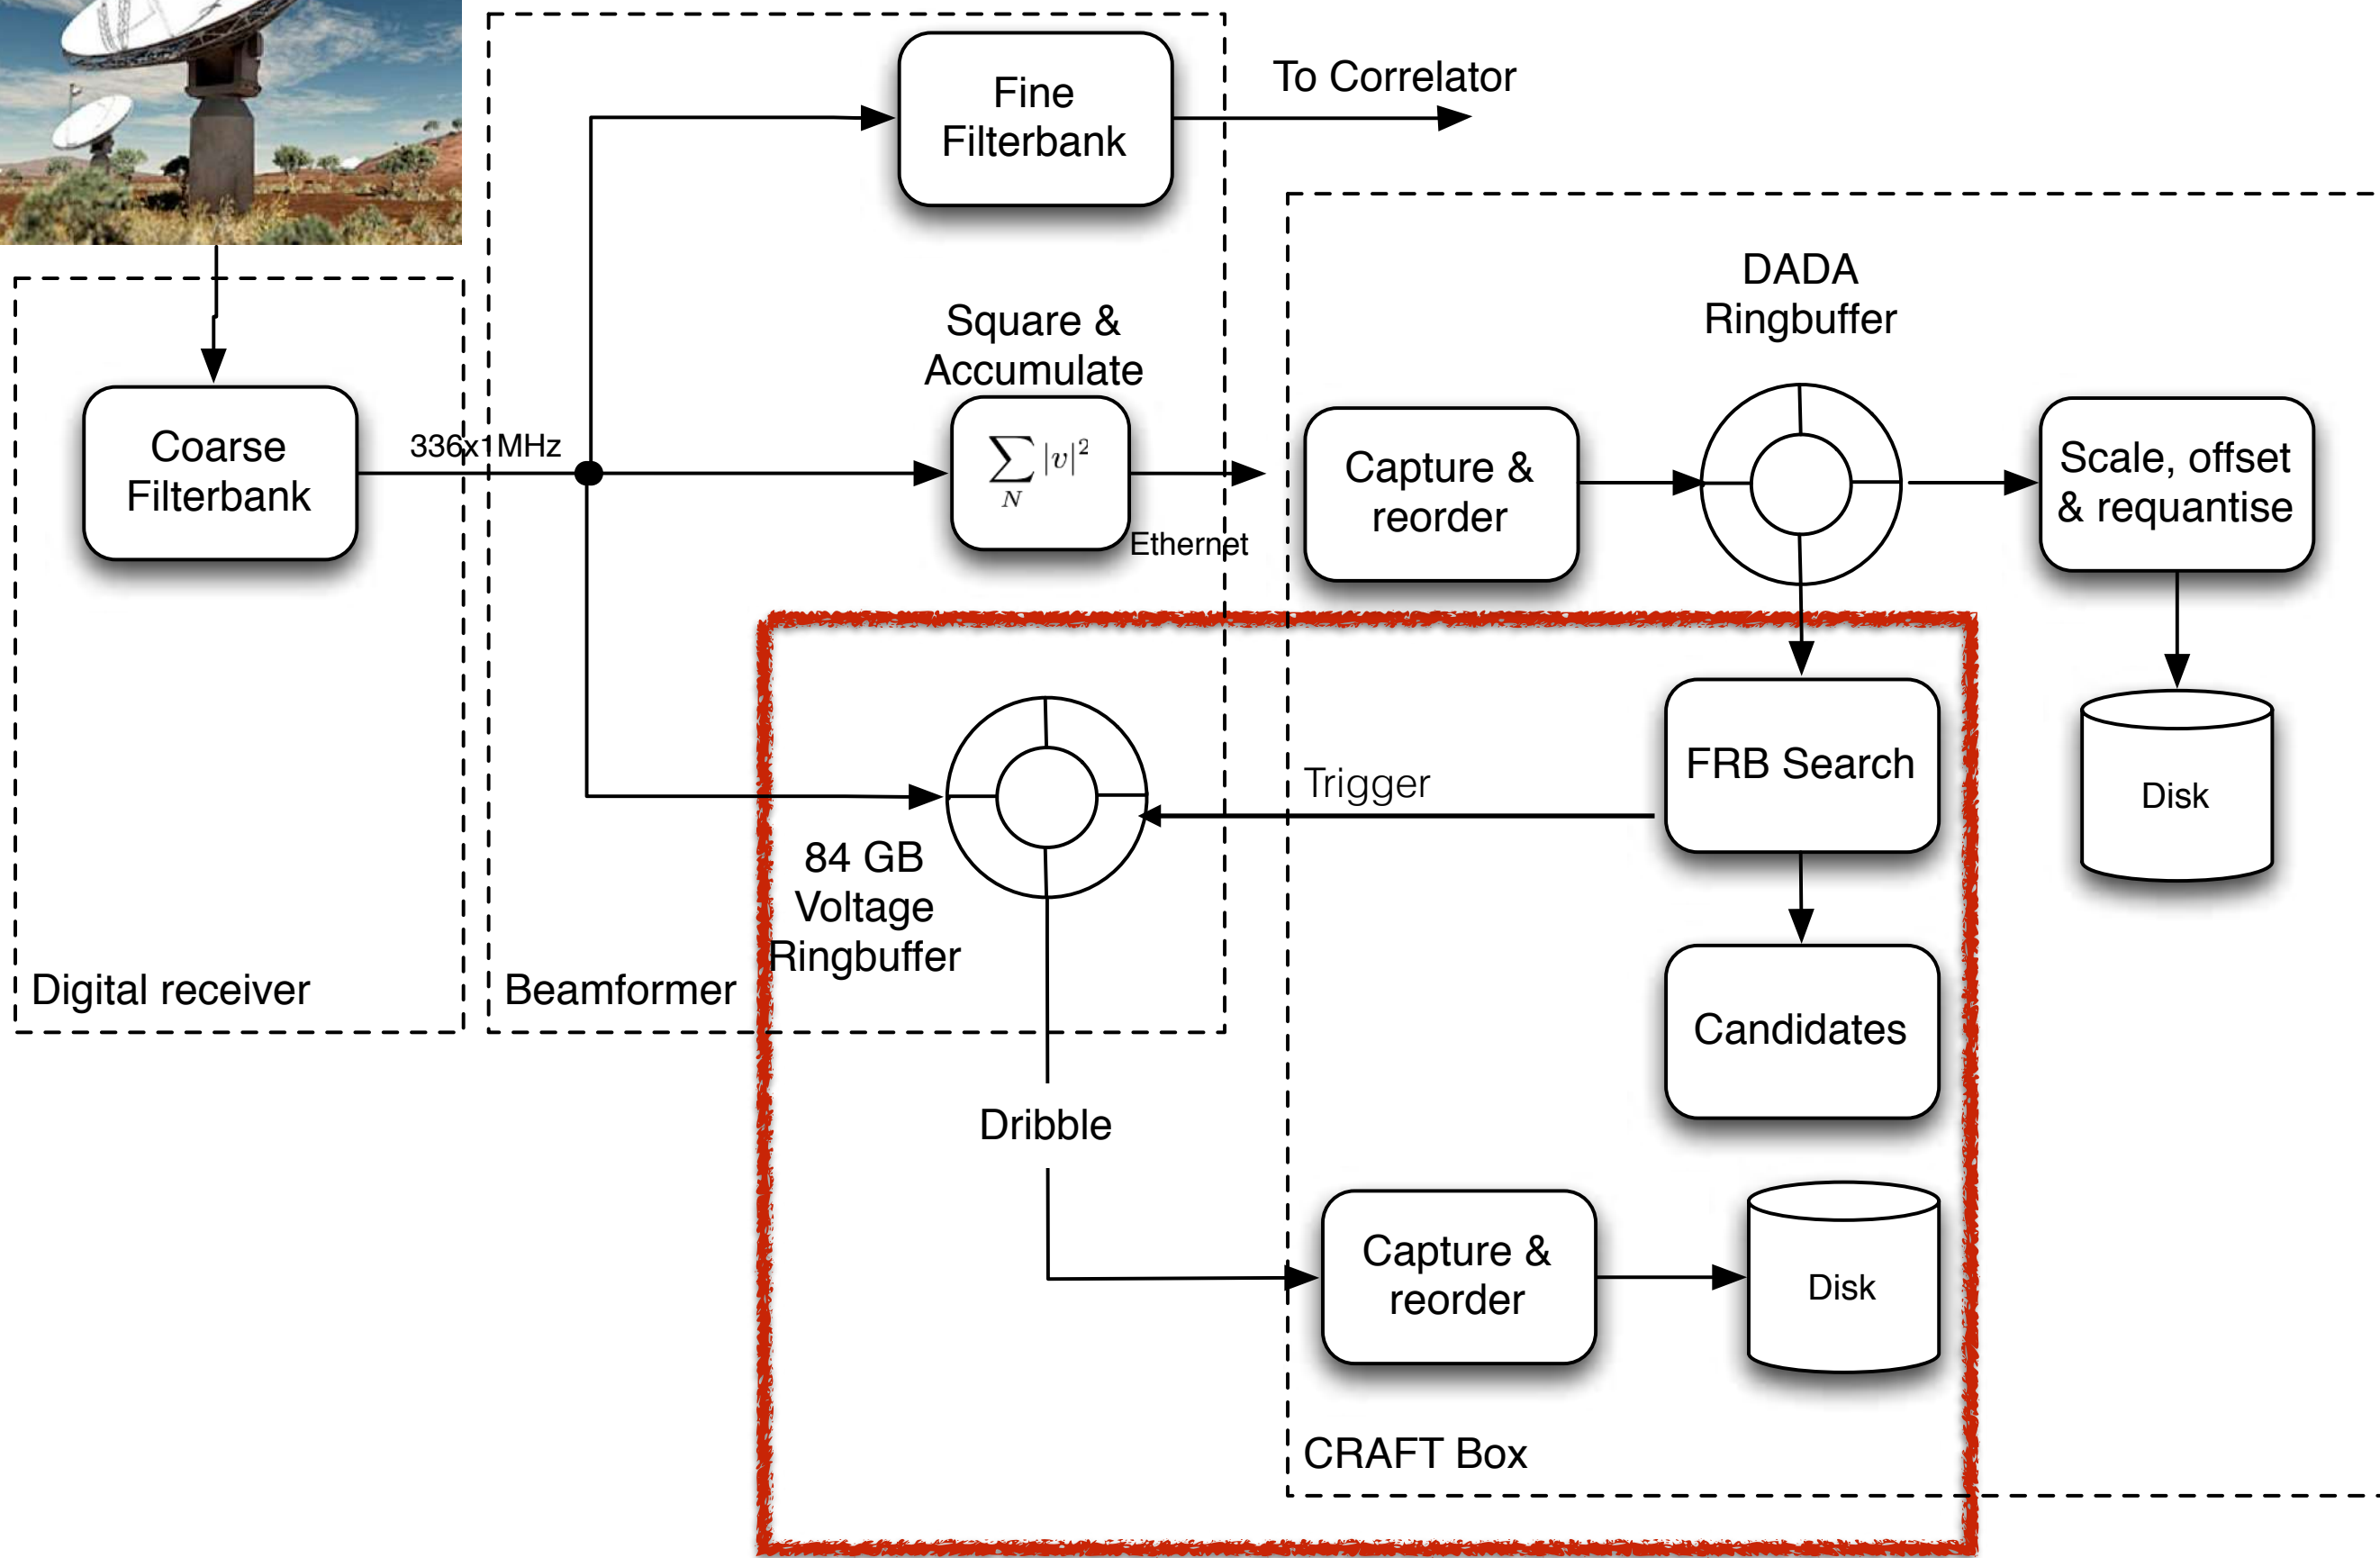

# ASKAP will be...

- 36 antennas
- 36 beams =  $\sim 30 \text{ deg}^2$  per antenna
- 336 x 1 MHz channels (only 300 for interferometry)
- Tuning: 700-1800 MHz
- $\sim 1\text{ms}$  time resolution

# CRAFT - the next step

# Innovation: Fly's-eye observing

# ASKAP's first 3 FRBs

**FRB 170107**  
DM: 609.5 pc cm<sup>-3</sup>

**FRB 170416**  
DM: 523.2(2) pc cm<sup>-3</sup>

**FRB 170428**  
DM: 991.7(8) pc cm<sup>-3</sup>

# FRB 170107

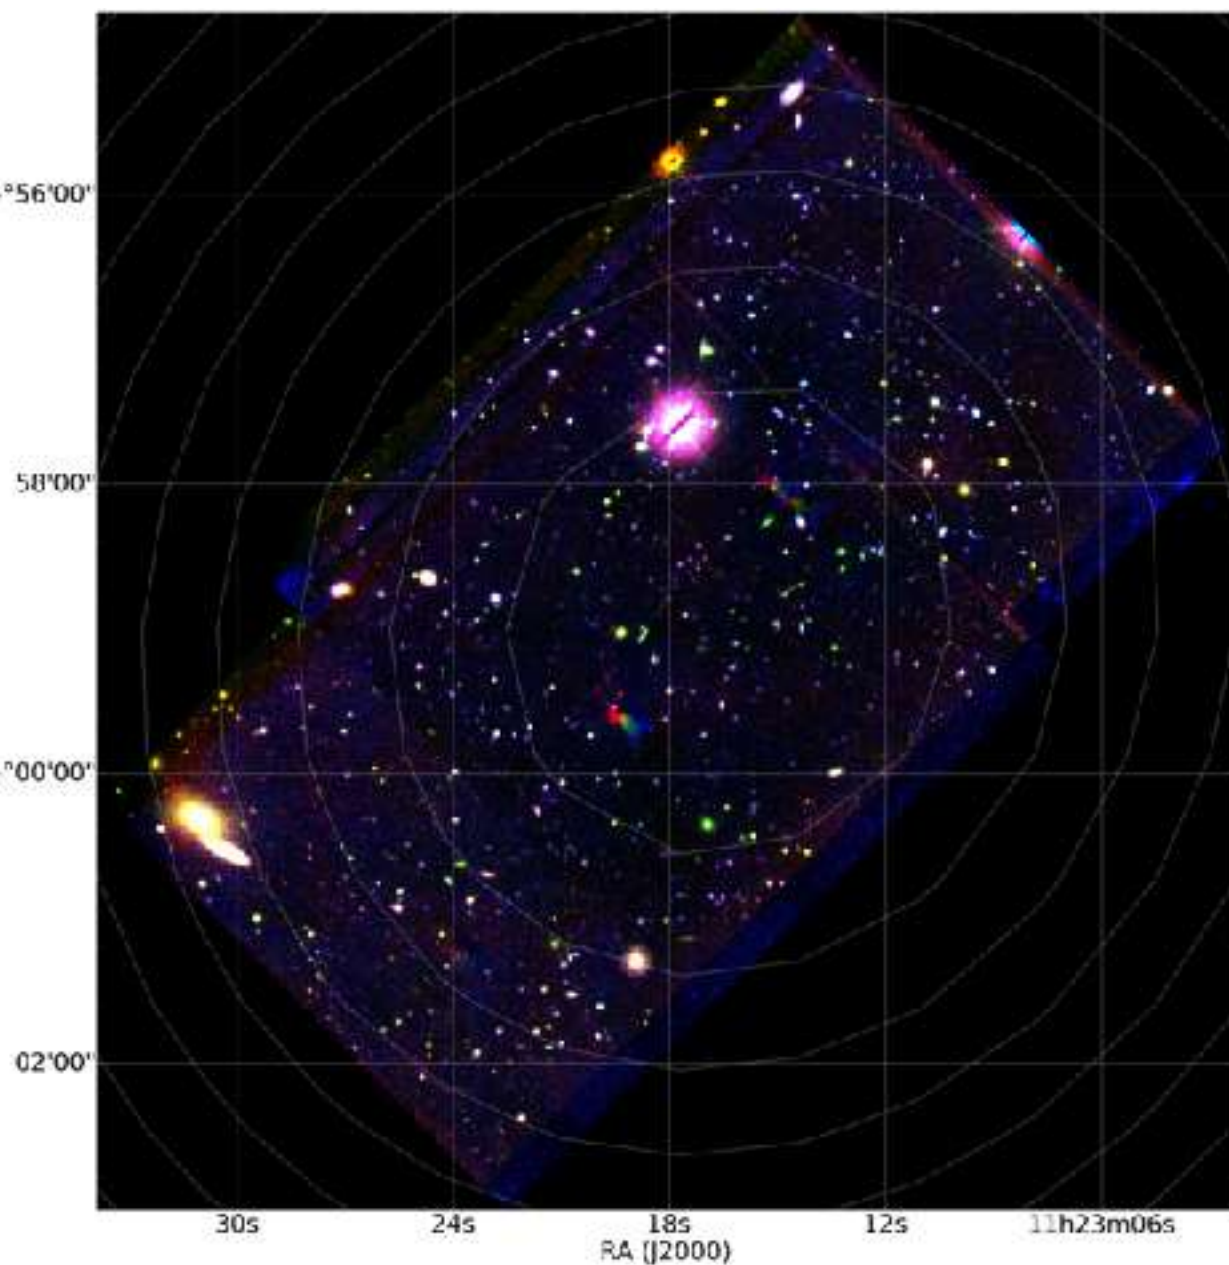

Spectral cutoff above 1.4 GHz  
DM=610 pc/cm<sup>3</sup>  
Fluence=58 Jy.ms

Localised to 8x8 arcmin  
- thanks to fully-sampled focal plane!

## Solar Radio Burst Classifications

TYPE	CHARACTERISTICS	DURATION	FREQUENCY RANGE	ASSOCIATED PHENOMENA
I	Short, narrow-bandwidth bursts. Usually occur in large numbers with underlying continuum.	Single burst: ~ 1 second Storm: hours - days	80 – 200 MHz	Active regions, flares, eruptive prominences.
II	Slow frequency drift bursts. Usually accompanied by a (usually stronger intensity) second harmonic.	3- 30 minutes	Fundamental: 20 – 150 MHz	Flares, proton emission, magnetohydrodynamic shockwaves.
III	Fast frequency drift bursts. Can occur singularly, in groups, or storms (often with underlying continuum). Can be accompanied by a second harmonic	Single burst: 1 - 3 seconds Group: 1 -5 minutes Storm: minutes - hours	10 kHz – 1 GHz	Active regions, flares.
IV	Stationary Type IV: Broadband continuum with fine structure	Hours - days	20 MHz – 2 GHz	Flares, proton emission.
	Moving Type IV: Broadband, slow frequency drift, smooth continuum.	30 – 2 hours	20 – 400 MHz	Eruptive prominences, magnetohydrodynamic shockwaves.
	Flare Continua: Broadband, smooth continuum.	3 – 45 minutes	25 – 200 MHz	Flares, proton emission.
V	Smooth, short-lived continuum. Follows some type III bursts. Never occur in isolation.	1-3 minutes	10 - 200 MHz	Same as type III bursts.

NOTES: In nearly all cases, drifting bursts drift from high to low frequencies.  
The Frequency Range is the typical range in which the bursts appear – not their bandwidth.  
The sub-types of type IV are not universally agreed upon and are thus open to debate.

# Summary

- It's an exciting time in radio transients (and variables)
- Know your telescope and your data
- Follow crazy ideas
- Work with wacky people - it's fun!
- The most useful equation in radio astronomy is  $\theta = \frac{\lambda}{D}$
